

DATA-DRIVEN CONTROL OF ENERGY STORAGE

Power Engineering Advanced Research Lab

The Research Questions?

How can we **control energy storage to 'play nicely' with other devices?**

How can we **maximize performance of energy storage in low inertia systems?**

Why RTDS/Real-Time Simulation

First stages of testing

Quickly gather datasets

Scope for expanding, PHIL/CHIL

Presentation Outline

Introduction of Data-Driven Control

The problem – Grid Supporting Energy Storage

Solving the problem with Data-Driven Control

Results and Conclusions

Introduction of Data-Driven Control

Two Approaches to Tuning Controllers

MODEL-BASED

- Physics - Differential equations
- Unmodelled dynamics
- Pre-construction
- Deep underlying knowledge of the system

DATA-DRIVEN

- Heuristic Tuning - Zeigler-Nichols PID tuning – 1942
- System Identification
- Requires the system for testing (constructed or accurate simulation)

Presentation Outline

Introduction of Data-Driven Control

Problems – Grid Supporting Energy Storage

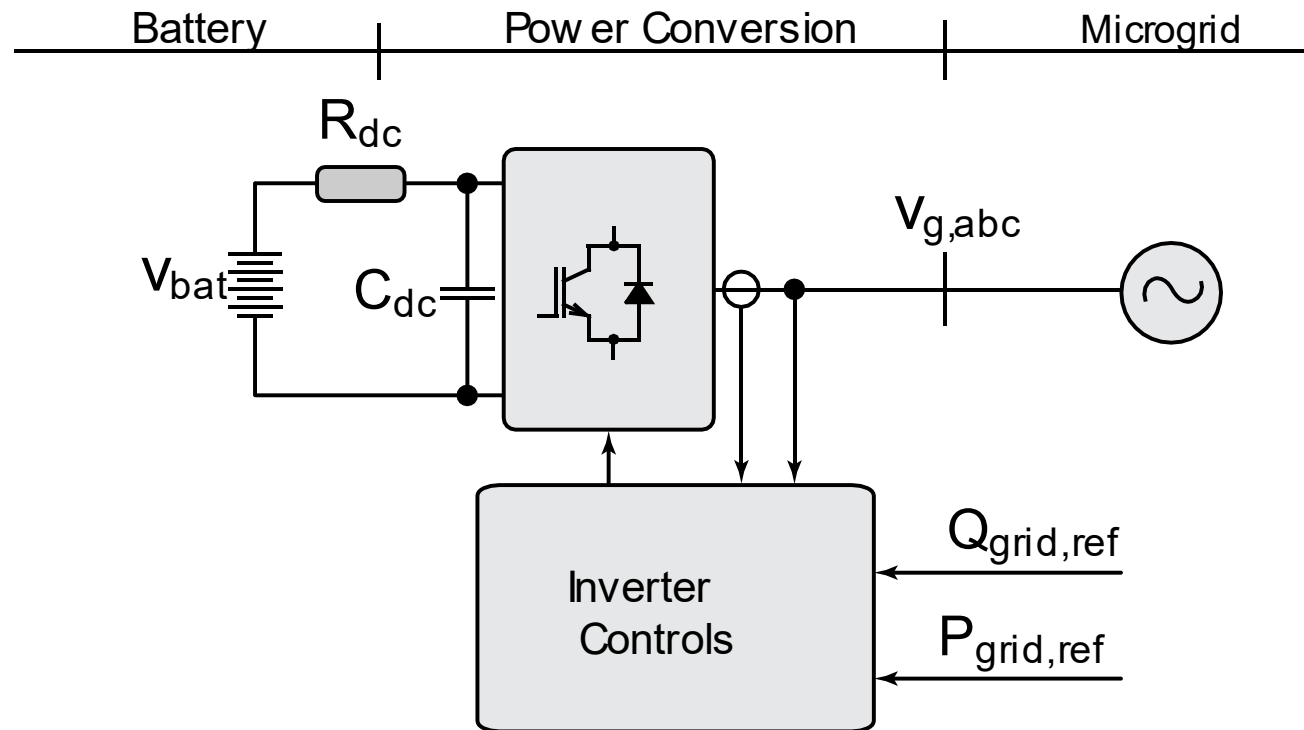

Applying Data-Driven Control

Results and Conclusions

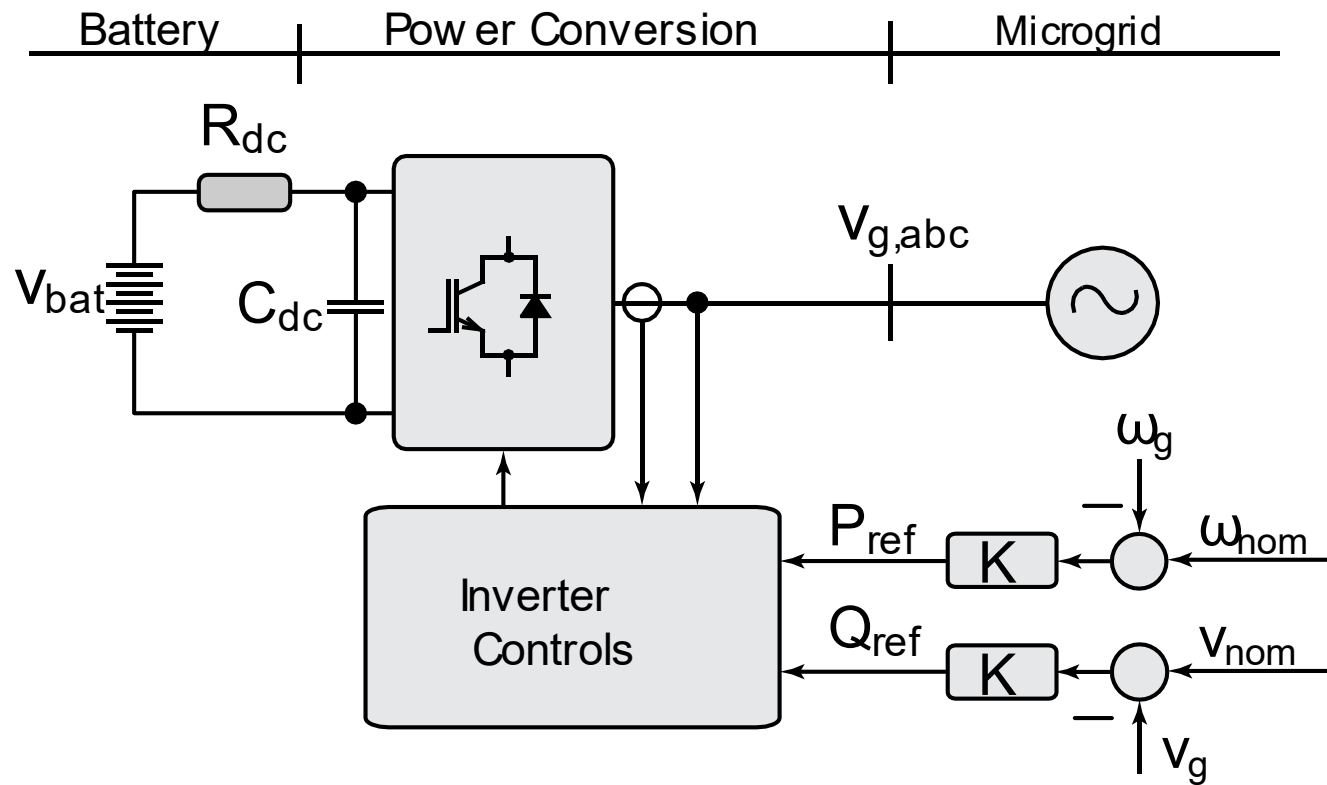

Problems – Grid Supporting Energy Storage

What is a Grid-Following Inverters?

Droop Control of Grid Following Inverters

Shipboard Power System

Generators, 250kW,

BESS, 100kW cont., 300kW (5s)

Changing Droop Gain of BESS

Initially, entire system is operating with 5% droop

250kVA load step pf 0.8

2.5% droop – BESS only, 5% droop Generators

Increase Gain of Battery + Generators

2.5% droop – 250kVA load step pf 0.8

What happens if the battery disconnects?

System becomes unstable

Presentation Outline

Introduction of Data-Driven Control

Problem – Grid Supporting Energy Storage

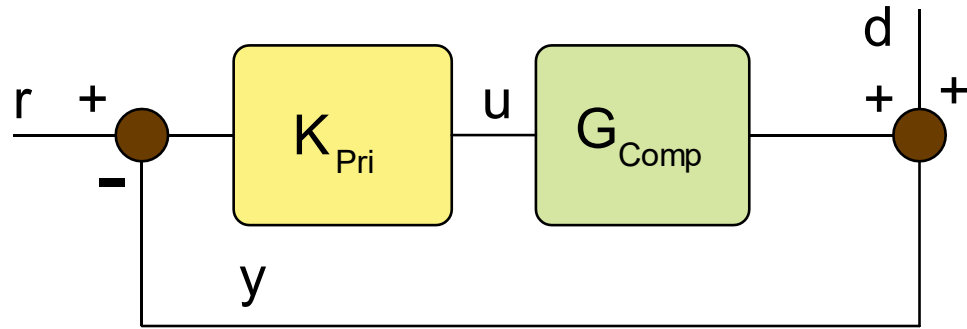

Applying Data-Driven Control

Results and Conclusions

Applying Data Drive Control

Thinking More like a Control systems Engineer

Integrator

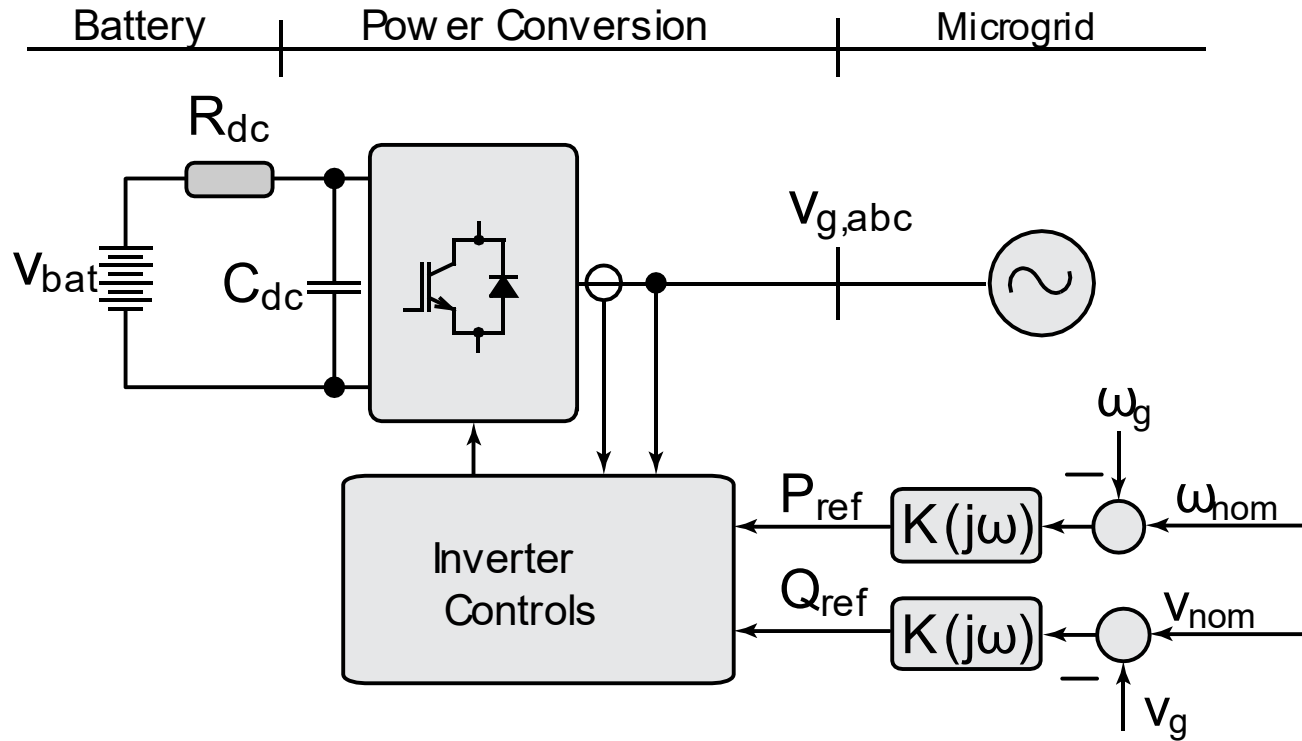

$$H_{int}(s) = \frac{1}{s}$$

Pole at $s = 0$

The 'droop' constraint is:

All devices in the network must have controller gain that is proportional to their power rating, **at 0 Hz**.

Alternative Controller Structure

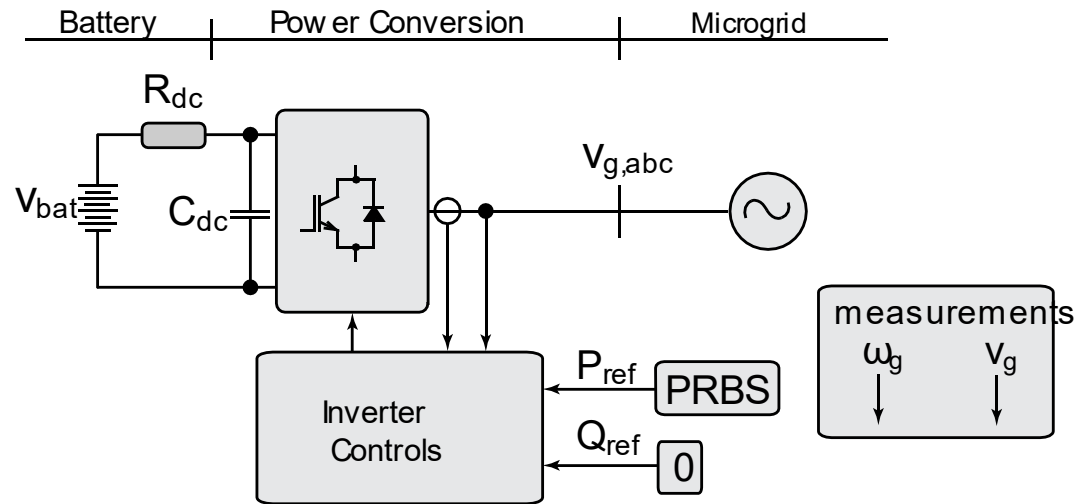

$$K(s) = \frac{a_0s + a_1s + \dots}{b_0s + b_1s + \dots}$$

$$K(z) = \frac{a_0z + a_1z + \dots}{b_0s + b_1s + \dots}$$

But, now we have more parameters to tune

System Identification - RTDS

First we need to know something about the plant

PRBS

System Identification - RTDS

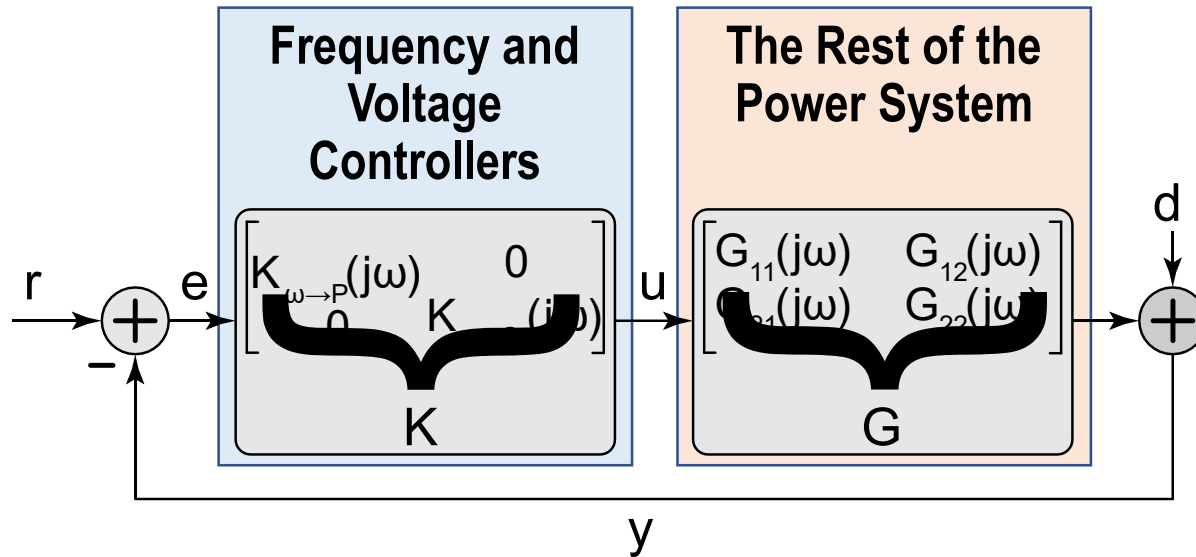

Then, with a little Fourier analysis (just mathematic some transforms)

$$G(j\hat{\omega}) = \frac{DFT(R_{uy})}{DFT(R_{uu})}$$

This can be accomplished in other ways! Doesn't have to be PRBS

Data Driven Control

What about droop?

Constrain
 $K(j\omega = 0)$

Performance in the Frequency Domain

Bandwidth, Gain Margin, Phase Margin, Disturbances, Sensitivities.....

Invaluable Textbook [3] – Feedback Control Theory

Tuning The Controller

Performance in the Frequency Domain

Optimisation of controllers parameters.

Solve an Optimisation Problem to Tune the Parameters

We minimised the
frequency response for
 $d \rightarrow e$

What about droop?
Constrain
 $K(j\omega = 0)$

There is a Matlab toolbox from EPFL for this
optimisation – [2]

https://www.epfl.ch/labs/la/research/page-67797-en-html/page-67814-en-html/fdrc_toolbox/

Results and Conclusion

Testing Platform

Simulate Power System

Timestep 50us

Controller

Lives in a c-function block running at 1ms

```
// -----  
// Place C code here which runs on the RTDS. The  
// code below is entered once each simulation  
// step.  
// -----  
allocateMemory(error,16); // memory allocated in 32 bit words  
allocateMemory(output,16); // 2 x 32 bit words per double  
  
if(step%Steps == 0) {  
  for(counter=1; counter<8; counter++){  
    output[counter] = output[counter-1];  
    error[counter] = error[counter-1];  
  }  
  error[0] = err;  
  
  for(counter=0; counter<8; counter++){  
    if(error[counter] > 10000) {  
      error[counter] = 10000;  
    }  
    if(output[counter] > 10000) {  
      output[counter] = 10000;  
    }  
  }  
  
  cont = b0*error[0] + b1*error[1] + b2*error[2]  
+ b3*error[3] + b4*error[4] + b5*error[5] - (a1*output[1] + a2*output[2] + a3*output[3] + a4*output[4]  
+ a5*output[8]);  
  output[0] = cont;  
}  
step++;  
  
// ----- End of CODE: Section -----
```

Data-Driven Controller

250kVA load step pf 0.8, 5% droop Generators

Data-Driven Controller

Generator Failure, 5% droop Generators

Conclusions

Fast and accurate simulations enable data-driven control

- Quickly gather datasets for different inputs/outputs
- Heuristic methods for tuning control systems have limitations.
- Faster systems (i.e. low inertia) systems, require improved methods for tuning controllers. Simply increasing gains lowers stability margins.

Data-driven control methods require less knowledge of underlying system

- Improved tuning for black or grey box systems.

QUESTIONS

Research Scope

Grid-Following Inverters

Microgrids

Primary Control Systems

Linear Control Systems

Future Work

Future Work:

- Applying to systems with multiple BESSs.
- Applying to larger power systems.
- Gathering knowledge of good performance criterion.
- Testing frequency and voltage control methods experimentally, via HiL tests.

Frequency vs time Domain

A change in the way of thinking:

- Time domain
- Frequency domain

Frequency Domain:

- Can handle dead times/delays well
- Good stability proofs/ definitions for robustness
- Better knowledge of the system than step response
- Better methods for dealing with multi-input multi-output systems

More About Control Design Tools

Can be used for other control problems, some examples:

- Inverter control systems - Current controllers and DC-link voltage controllers.
- Motion control - gyroscopes
- Damping inter-area oscillations
- UPS/ voltage controlled inverters
- High precision Magnet Power Supply

What if the Power System Changes?

Comparing Identified FRD for at Different Load

- Simulation lets you identify the power system at many different operating points. The can all be incorporated into optimisation.

More About These Tools

Can be used for other control problems, some examples:

- Inverter control systems - Current controllers and DC-link voltage controllers.
- Motion control - gyroscopes
- Damping inter-area oscillations
- UPS/ voltage controlled inverters
- High precision Magnet Power Supply

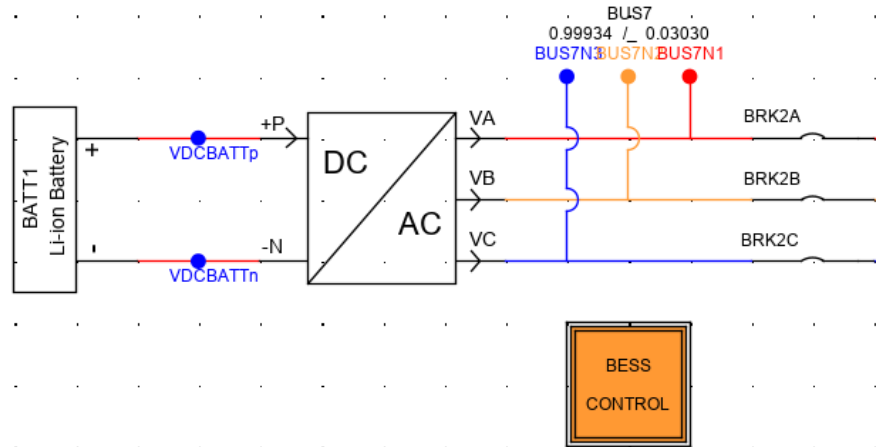

More About Test System

The screenshot displays the Simulink Component Builder 5.008 interface. The main workspace shows a 'Discrete Controller' block on a grid. The right-hand pane is open to the 'Parameters' tab, showing a table of parameters for the 'Difference_Equation' component.
